Best Answer: A "transient" solution to a differential equation is a solution that describes the behavior of the dependent variable for times "close" to  $t = 0$ . In contrast, the "long-time" or "steady-state" solution, which is usually simpler, describes the behavior of the dependent variable as  $t \rightarrow \infty$ .

The difference between a steady state simulation and marching a transient solution to steady state is that the SS simulation ignores many of the cross terms and higher order terms dealing with time. These terms all go to zero in steady state so they don't affect the steady state result. The transient simulation includes all these terms.

The steady state solution is shown in blue and the steady-state plus transient is shown in red. These transient terms in the solution, when they are significant, are sometimes called the transient solutions. In many physical problems, the transient solution is the least important part. However, there are cases where it is of major importance.

Transient Solution, Driven Oscillator The solution to the driven harmonic oscillator has a transient and a steady-state part. The transient solution is the solution to the homogeneous differential equation of motion which has been combined with the particular solution and forced to fit the physical boundary conditions of the problem at hand.

Transient finite element solutions are often validated by comparing the time history to analytical solutions where a surface temperature changes instantly from its initial condition (IC) value to a different value set by an essential boundary condition (EBC), or where a sudden heat flow into the surface occurs.

formulation of the one-dimensional transient temperature distribution  $T(x,t)$  results in a partial differential equation (PDE), which can be solved using advanced mathematical methods. For plane wall, the solution involves several parameters:  $T = T(x, L, k, \alpha, h, T_i, T_\infty)$  where  $\alpha = k/\rho C_p$ .

Abstract. In this chapter, we apply the RG-factorizations to provide a unified algorithmic framework for dealing with transient solution in stochastic models. The transient solution includes the transient probability, the first passage time, the sojourn time and time-inhomogeneous Markov chains.

because . Thus, the driven response oscillates at the resonant frequency, , because both the time asymptotic and transient solutions oscillate at this frequency. However, the amplitude of the oscillation grows monotonically as , and so takes a time of order to attain its final value , which is, of course, larger than the driving amplitude by the resonant amplification factor (or quality factor), .
